## Imaging Information (continued)

### Study Result (continued)

Technique: CT scan of the abdomen and pelvis was performed after the administration of oral and 75 mL nonionic contrast. Automated exposure software was utilized for dose reduction.

No relevant priors.

Findings: Evaluation of the visualized portions of the lung bases demonstrates no evidence of a focal infiltrative or consolidative process.

Within the subcapsular region of the left hepatic lobe, there is a low-attenuation lesion measuring up to 16 mm. This demonstrates subtle peripheral nodular discontinuous enhancement. Additional lesion which demonstrates peripheral nodular discontinuous enhancement is seen within the posterior aspect of the right hepatic lobe measuring up to 2.5 x 3.8 cm. Smaller of the 2 lesions partially fills in on the delayed phase imaging. Larger of the 2 lesion fills in with contrast on the delayed phase imaging. These are most compatible with hemangiomas. The gallbladder appears normal. There is no biliary ductal dilatation.

The spleen is normal in size.

Pancreas and bilateral adrenal glands appear normal.

The kidneys enhance homogeneously and symmetrically. Neither kidney demonstrates evidence of hydronephrosis or calculi. There are bilateral renal cysts. Largest cyst is located within the mid to upper pole region of the left kidney posteriorly measuring up to 5.3 cm. There is no hydronephrosis on either side. Neither kidney demonstrates evidence of a solid mass. Kidneys enhance homogeneously and symmetrically. There is symmetric renal excretion of contrast seen bilaterally.

The abdominal aorta demonstrates a normal course and caliber without evidence of aneurysmal dilatation.

Urinary bladder appears grossly unremarkable. There is posterior inferior impression on the bladder by the prostate gland. The prostate gland measures up to 5.2 x 3.9 cm.

There is no evidence of bowel wall thickening, and no evidence of a bowel obstruction. There are a few sigmoid colon diverticula, without CT evidence of diverticulitis. The appendix is well-visualized and appears normal.

There is no free intraperitoneal air or fluid.

Evaluation of the visualized osseous structures demonstrates no evidence of a suspicious osteolytic or osteoblastic process. There are mild multilevel degenerative changes and disc disease.
